BLUEBRIGDE DIGITAL BANKING PERFORMANCE ANALYTICS

PRESENTED BY: VICTORIA ADEMIJUBE

Problem Statement

- Customers are complaining of failed transactions despites having sufficient funds.
- Flagged transactions are being processed instead of being blocked.
- The management wants to know if the 5G network slicing is delivering expected performance benefits.
- The management has to choose from mobile app and desktop portal for the next quarter, due to limited budget.

Objective

- Identify the root cause of declining transaction approval rates.
- Compare the number of flagged transactions to blocked transactions.
- Determine whether premium network slices outperform the standard slice.
- Evaluate the success and failure rates of mobile app and desktop portal.

Dataset Overview

Data Source

- Transaction Dataset
- 40000 rows and 14 columns

Data cleaning

- No rows with errors
- No duplicates rows
- No missing values
- No data inconsistencies

Methodology

Tools & Techniques

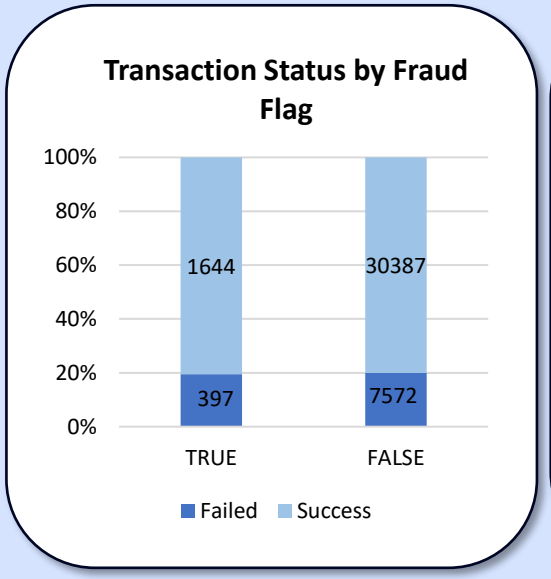
- Microsoft Excel (Pivot Tables, Pivot Charts, Slicers).
- Data cleaning and transformation in Excel.
- Dashboard layout and visualization best practices.
- Basic descriptive analytics and KPI design.

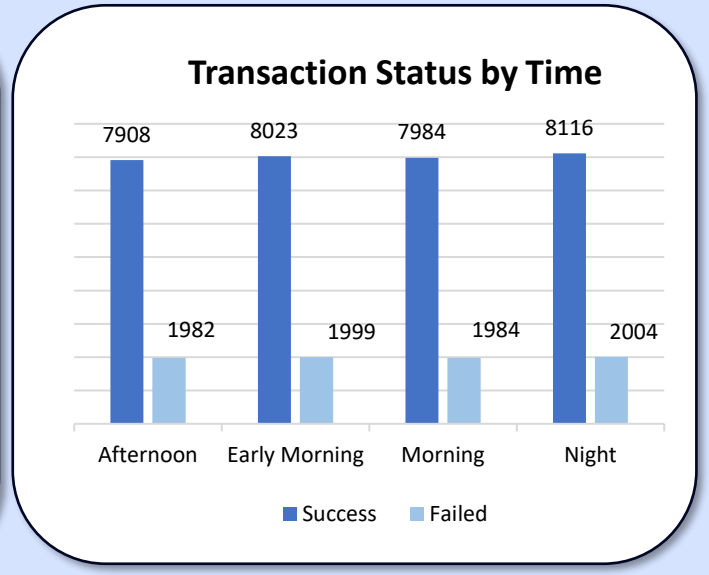
- Columns such as Latency, Slice bandwidth, and Hour of the day were grouped.
- Failure rate was calculated

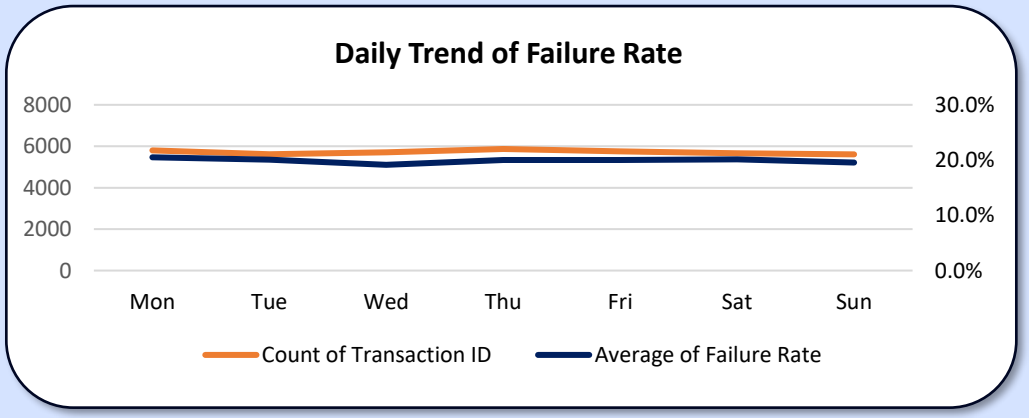
Data Insight

- Total transactions : 40000
- Total senders : 32269
- Total receivers : 32230
- Average failure rate: 19.9%
- 7969 (20%) transactions were not successful.
- 2041 (5%) transactions were flagged as fraud.

Data Insight

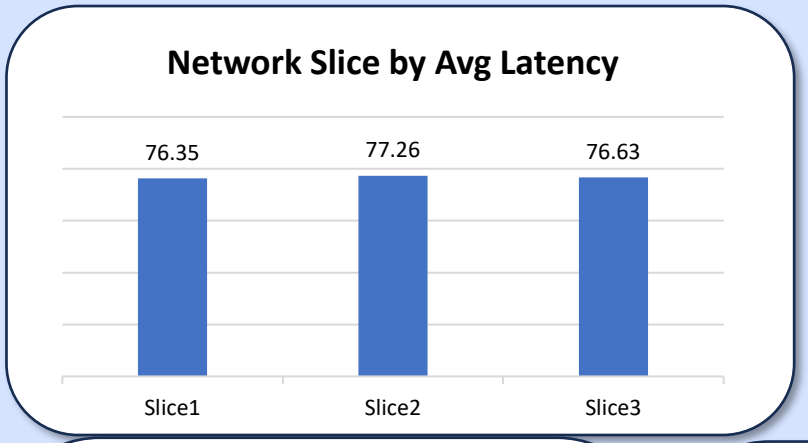


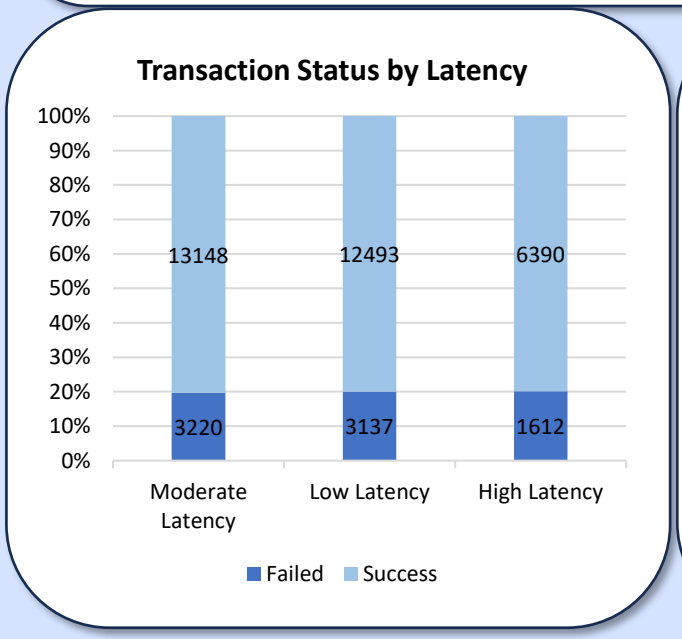


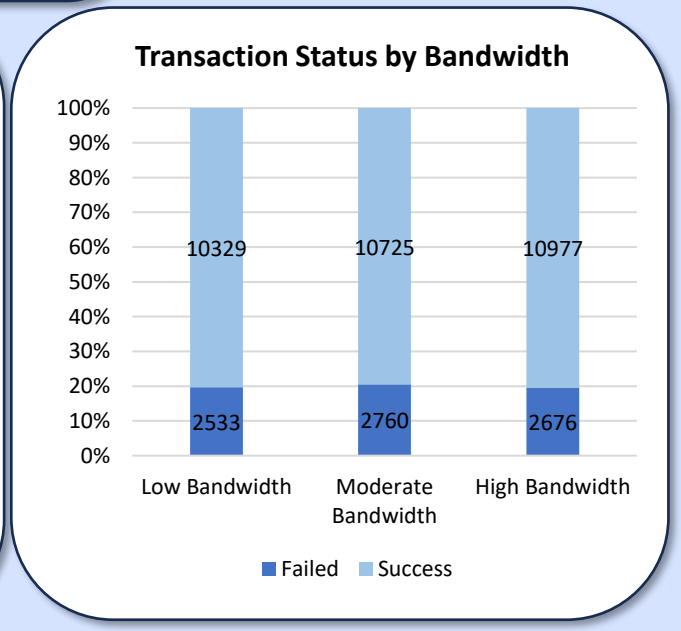


- 1644 flagged transactions were successful while 7572 transaction were not flagged but failed.
- The failure counts follow the same pattern at different time of the day.
- Average failure rate is consistently around 19.1%-20.5% daily.

Data Insight

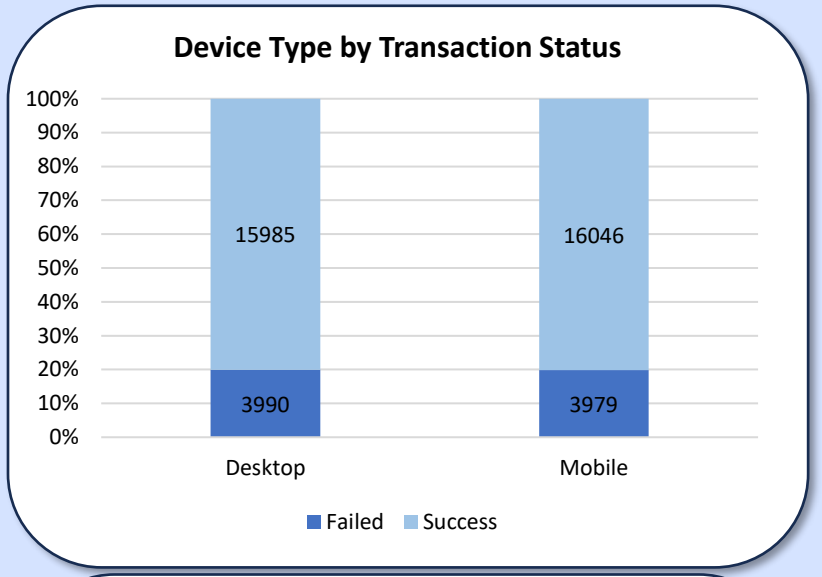


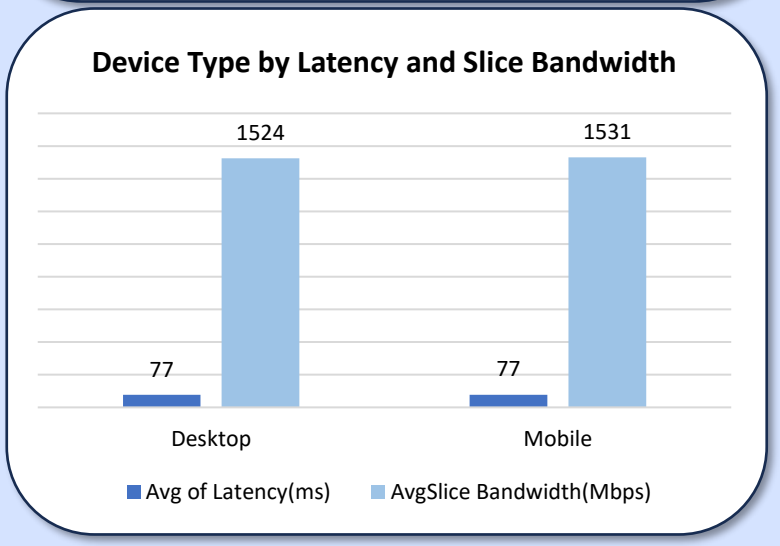




- The 3 network slices have similar latency.
- This means that the premium investment does noy have any impact on the network speed.
- The count of failed transactions across low, moderate and high latency and bandwidth are almost uniform.

Data Insight





- Failure occurs at the same rate across device types.
- Both desktop portal and mobile app have similar average latency and slice bandwidth.
- All these suggests that failed transactions is not significantly affected by the day, time of the day, device type, latency and network slice.
- This could be a systemic error.

Recommendation

- Stakeholders should get more data on banking transactions.
- Software developer should be contacted to improve banking online platform.

THANK YOU
